Rapid evolution in the parasitic protist Leishmania as revealed by microsatellite data. Parasitic

protists are of key importance to the evolution of host-parasite associations. The speciation process of these parasites is generally assumed to involve increased host specificity, reduced recombination, and stable transmission, all of which tend to promote the accumulation of small genetic changes over time. We used microsatellite data from nine loci to study the genetic diversity of the human-pathogenic protist parasite *Leishmania major*. We estimated that the parasite

population under study evolved with a mean rate of $0.096 \pm 0.014\%$ per year, a rate comparable with that reported for other highly host-specific parasites. We show that an outbred parasite population, rather than an inbred population, must have been the source of the diversity. However, we note that the levels of heterozygosity found in *Leishmania* 50b96ab0b6
